

Supplementary Chapter: The Mechanical Background Noise (The NANOGrav Anomaly)

Author: Andrew Robus **Status:** *Supplement for Discussion (Work in Progress)* **Date:** May 14, 2026

1. The Observation: The Hum of the Universe

Between 2023 and 2024, international research teams (including NANOGrav) published data confirming a permanent, low-frequency background noise of gravitational waves. The enigma: this "hum" is significantly more intense than standard physics can explain through the mere merging of black holes. In academic circles, this is often referred to as an "unknown energetic component."

2. The Solution in Andrew's Ground

In a purely mechanical universe, this noise is not a mystery but a physical necessity. If space is a physical 4D medium (QGP), any dynamics within this medium must generate vibrations. Andrew's Ground offers three mechanical coupling pathways that could be responsible for the measured intensity, either individually or in combination:

A. The Micro-Tremor of the QGP Anchors

Every elementary particle is directly connected to the 4D medium via its QGP core. Any movement of matter within our 3D bubble forces the 4D anchor to move within the medium.

- **The Effect:** The trillions of particles in a galaxy act like tiny paddles in an ocean. While standard physics only counts the "heavy strikes" (black holes), Andrew's Ground sums up the micro-noise of all matter anchors.

B. Thermal Expansion (Dark Energy)

As described in the main work, 3D space absorbs thermal energy from the 4D background, leading to expansion.

- **The Effect:** This energy flow occurs at the boundary layer between the 3D skin and the 4D core. Such an energetic exchange process is never mechanically perfectly smooth; it generates turbulence at the membrane, which would be measurable as background noise.

C. Hydrostatic Buoyancy (Time-Drift)

The theory postulates that our universe "rises" due to the density gradient within the QGP sea (the cause of the flow of time).

- **The Effect:** A movement of this magnitude through an incompressible medium inevitably generates hydrodynamic wavefronts. In this case, the "hum" would be the sound of the universe sliding through the 4D medium.

3. Preliminary Conclusion and Outlook

At this stage, it is not yet possible to isolate the exact contributions of these three mechanisms to the overall signal. However, it is probable that the observed "excessive" intensity of the noise is the result of an overlap of these effects.

While standard physics must search for increasingly exotic black holes to explain the data, Andrew's Ground provides a simple, hardware-based answer: **The medium itself vibrates because it is working.**
