Modern astrophysics faces a riddle that it conceals behind elegant mathematical phrases: it postulates that mass curves space and particles follow this curvature. But when one asks for the *why*—the actual mechanical gears that enforce this movement—one is met with silence. In *Andrew's Ground*, we have replaced this postulate with tangible hardware: every elementary particle in our three-dimensional world is linked via a fundamental connection (an anchor or pressure column) to the surrounding Quark-Gluon Plasma sea (QGP).

Yet one decisive question remained open: Why is this pull radial? What fundamental mechanism forces every single QGP anchor in the universe to pull stubbornly and relentlessly toward the center of the sphere?

The answer does not lie in abstract, magical remote action. The answer lies in one of the simplest and most powerful mechanical properties of liquids: **surface tension**.

## The Axiom of the Macroscopic Sphere

To understand the cause of gravitation, we must consider the geometry of the entire system. The QGP sea is not an infinite, flat wall. In physical reality, nothing angular or infinitely flat exists on its own. Every system under the influence of its own energy and hydrostatic dynamics strives for the most symmetrical form: the sphere.

The QGP sea is a gigantic, three-dimensional sphere floating stably in the absolute vacuum of the next higher dimension. It requires no artificial mathematical vessels, such as Anti-de Sitter space, to hold it together. Like a massive star, this QGP sphere is in perfect hydrostatic equilibrium: the gargantuan gravitation of its own mass pulls everything inward, exactly balancing the thermal explosive force of the hot plasma.

At the outermost boundary of this gigantic sphere, exactly what we observe on a small scale with a water droplet in zero gravity occurs: a sharp interface is formed against the absolute nothingness of the external vacuum.

## The Mechanics of Radial Pull

Consider the molecular mechanics of a liquid surface. A particle deep inside the medium is pulled equally from all sides by its neighboring particles. The forces cancel out; the particle is in equilibrium.

However, a particle at the surface has no neighbors on the outside. It experiences a net pull directed exclusively inward, perpendicular to the surface, toward the center of the sphere. Since the QGP sea

is a nearly perfect, incompressible fluid with an extremely strong inherent interaction between quarks and gluons, this interface generates a fundamental, unimaginably powerful cosmic surface tension.

This macroscopic surface tension acts like a giant, invisible hand, permanently and radially compressing the entire medium. Every particle inside the sea is under this permanent, center-directed pressure.

## The Anchor as a Channel of Primordial Force

Our three-dimensional world (whether as a bubble or an expanding gamma-ray burst jet) exists within this flowing medium. Our elementary particles are not isolated objects; they are local vortices and interfaces within the QGP.

Since every quark is inseparably connected to the medium, the permanent, radial pulling force of the cosmic surface tension is transmitted one-to-one to the anchors of our matter.

- **Flat Space:** If a particle is in an empty region of the vacuum, its QGP anchor experiences the uniform, radial base pull of the cosmic surface tension toward the spherical core. The particle remains in its natural inertial path.
- **Massive Objects (Channeling):** When matter in 3D space clusters into stars or planets, these quark interfaces displace and compress the viscous QGP medium locally. This local disturbance alters the hydrostatic gradient. The large-scale, radial contraction of the surface tension is channeled and amplified at this point.

What Albert Einstein formalized mathematically as the "curvature of spacetime" is, in truth, the mechanical effect of this amplification. Gravitation is not an independent fundamental force of nature. It is nothing more than the macroscopic manifestation of the surface tension of the QGP background.

## Conclusion: The End of Ghost Forces

With this insight, the mechanical circle of *Andrew's Ground* is closed. We no longer require hypothetical gravitons, immaterial spacetime sheets, or infinite mathematical singularities.

The universe functions according to the same undeniable laws of hydrodynamics as a water droplet or a lava lamp. We do not fall to the ground on Earth because the mass of the Earth "attracts" us across empty space. We are pushed to the ground because the mass of the Earth locally bundles the radial, inward-directed pressure of the cosmic surface tension of the QGP sea. We exist and have weight because the entire medium in which we swim is under permanent mechanical pressure.
